Statistical Computing

Managing data frames with the dplyr package

Feng Li feng.li@cufe.edu.cn

School of Statistics and Mathematics Central University of Finance and Economics http://feng.li

Data Frames

- data frame is a key data structure in statistics and in R.
- one observation per row and each column represents a variable
- we need to have good tools for dealing with them.
- you have seen subset() function and the use of [and \$
- dplyr package is designed to mitigate a lot of complex operations for data frames.

The dplyr Package

- by Hadley Wickham of RStudio
- everything dplyr does could already be done with base R, but it *greatly* simplifies existing functionality in R.
- it provides a "grammar" (in particular, verbs) for data manipulation and for operating on data frames.
- the dplyr functions are very fast, as many key operations are coded in C++.

dplyr Grammar

Some of the key "verbs" provided by the dplyr package are

- select: return a subset of the columns of a data frame, using a flexible notation
- filter: extract a subset of rows from a data frame based on logical conditions
- arrange: reorder rows of a data frame
- rename: rename variables in a data frame
- mutate: add new variables/columns or transform existing variables
- summarise / summarize: generate summary statistics of different variables in the data frame, possibly within strata
- %>%: the "pipe" operator is used to connect multiple verb actions together into a pipeline

Common dplyr Function Properties

All of the functions have a few common characteristics. In particular,

- 1. The first argument is a data frame.
- 2. The subsequent arguments describe what to do with the data frame specified in the first argument, and you can refer to columns in the data frame directly without using the \$ operator (just use the column names).
- 3. The return result of a function is a new data frame.

4. Data frames must be properly formatted and annotated for this to all be useful. In particular, the data must be tidy. In short, there should be one observation per row, and each column should represent a feature or characteristic of that observation.

Installing the dplyr package

```
install.packages("dplyr")
```

After installing the package it is important that you load it into your R session with the library() function.

```
library(dplyr)
##
## Attaching package: 'dplyr'
## The following objects are masked from 'package:stats':
##
## filter, lag
## The following objects are masked from 'package:base':
##
## intersect, setdiff, setequal, union
```

select()

We will use a dataset containing air pollution and temperature data for the city of Chicago in the U.S.

```
chicago <- readRDS("chicago.rds")</pre>
```

```
dim(chicago)
## [1] 6940
str(chicago)
## 'data.frame':
                   6940 obs. of 8 variables:
## $ city : chr "chic" "chic" "chic" "chic" ...
## $ tmpd
              : num 31.5 33 33 29 32 40 34.5 29 26.5 32.5 ...
## $ dptp
               : num 31.5 29.9 27.4 28.6 28.9 ...
               : Date, format: "1987-01-01" "1987-01-02" ...
## $ date
## $ pm25tmean2: num NA ...
## $ pm10tmean2: num 34 NA 34.2 47 NA ...
## $ o3tmean2 : num 4.25 3.3 3.33 4.38 4.75 ...
## $ no2tmean2 : num 20 23.2 23.8 30.4 30.3 ...
```

Sometimes you may want to use only a couple of variables out of many.

```
names(chicago)[1:3]
## [1] "city" "tmpd" "dptp"
subset <- select(chicago, city:dptp)
head(subset)
## city tmpd dptp
## 1 chic 31.5 31.500
## 2 chic 33.0 29.875
## 3 chic 33.0 27.375
## 4 chic 29.0 28.625
## 5 chic 32.0 28.875
## 6 chic 40.0 35.125</pre>
```

Sometimes you may want to drop some variables that are not useful.

```
select(chicago, -(city:dptp))
```

If you wanted to keep every variable that ends with a "2", we could do

```
subset <- select(chicago, ends_with("2"))
str(subset)
## 'data.frame': 6940 obs. of 4 variables:
## $ pm25tmean2: num NA ...
## $ pm10tmean2: num 34 NA 34.2 47 NA ...
## $ o3tmean2 : num 4.25 3.3 3.33 4.38 4.75 ...
## $ no2tmean2 : num 20 23.2 23.8 30.4 30.3 ...</pre>
```

Or if we wanted to keep every variable that starts with a "d", we could do

```
subset <- select(chicago, starts_with("d"))
str(subset)
## 'data.frame': 6940 obs. of 2 variables:
## $ dptp: num 31.5 29.9 27.4 28.6 28.9 ...
## $ date: Date, format: "1987-01-01" "1987-01-02" ...</pre>
```

filter()

The filter() function is used to extract subsets of rows from a data frame.

```
chic.f <- filter(chicago, pm25tmean2 > 30)
str(chic.f)
## 'data.frame':
                   194 obs. of 8 variables:
## $ city
             : chr "chic" "chic" "chic" "chic" ...
               : num 23 28 55 59 57 57 75 61 73 78 ...
## $ tmpd
## $ dptp
              : num 21.9 25.8 51.3 53.7 52 56 65.8 59 60.3 67.1 ...
              : Date, format: "1998-01-17" "1998-01-23" ...
## $ pm25tmean2: num 38.1 34 39.4 35.4 33.3 ...
## $ pm10tmean2: num 32.5 38.7 34 28.5 35 ...
## $ o3tmean2 : num 3.18 1.75 10.79 14.3 20.66 ...
## $ no2tmean2 : num 25.3 29.4 25.3 31.4 26.8 ...
summary(chic.f$pm25tmean2)
##
     Min. 1st Qu. Median
                             Mean 3rd Qu.
                                            Max.
                            36.63 39.53
                                            61.50
    30.05 32.12
                    35.04
```

We could for example extract the rows where PM2.5 is greater than 30 and temperature is greater than 80 degrees Fahrenheit.

```
chic.f <- filter(chicago, pm25tmean2 > 30 & tmpd > 80)
select(chic.f, date, tmpd, pm25tmean2)
##
           date tmpd pm25tmean2
## 1 1998-08-23
                 81
                      39.60000
## 2 1998-09-06

## 10 2002-07-18 82 38.85000
```

arrange()

The arrange() function is used to reorder rows of a data frame according to one of the variables/columns.

Here we can order the rows of the data frame by date, so that the first row is the earliest (oldest) observation and the last row is the latest (most recent) observation.

```
chicago <- arrange(chicago, date)</pre>
```

We can now check the first few rows

and the last few rows.

```
tail(select(chicago, date, pm25tmean2), 3)

## date pm25tmean2

## 6938 2005-12-29 7.45000

## 6939 2005-12-30 15.05714

## 6940 2005-12-31 15.00000
```

Columns can be arranged in descending order too by useing the special desc() operator.

```
chicago <- arrange(chicago, desc(date))</pre>
```

Looking at the first three and last three rows shows the dates in descending order.

```
head(select(chicago, date, pm25tmean2), 3)
##
           date pm25tmean2
## 1 2005-12-31 15.00000
## 2 2005-12-30 15.05714
## 3 2005-12-29
                 7.45000
tail(select(chicago, date, pm25tmean2), 3)
##
             date pm25tmean2
## 6938 1987-01-03
                           NA
## 6939 1987-01-02
                           NA
## 6940 1987-01-01
                           NA
```

How would you do this in base R without dplyr?

rename()

Renaming a variable in a data frame in R is surprisingly hard to do! The rename() function is designed to make this process easier.

Here you can see the names of the first five variables in the chicago data frame.

Now we rename the awkward variable names.

mutate()

The mutate() function exists to compute transformations of variables in a data frame.

For example, with air pollution data, we often want to detrend the data by subtracting the mean from the data

```
chicago <- mutate(chicago, pm25detrend = pm25 - mean(pm25, na.rm = TRUE))
head(chicago)
   city tmpd dewpoint
                             date
                                     pm25 pm10tmean2 o3tmean2 no2tmean2 pm25detrend
## 1 chic

                                                                           7.329042
## 6 chic
           35
                  29.6 2005-12-26 8.40000
                                              8.5 14.041667 16.81944
                                                                           -7.830958
```

group_by()

The group_by() function is used to generate summary statistics from the data frame within strata defined by a variable. For example, in this air pollution dataset, you might want to know what the average annual level of PM2.5 is.

First, we can create a year varible using as.POSIX1t().

```
chicago <- mutate(chicago, year = as.POSIXIt(date)$year + 1900)</pre>
```

Now we can create a separate data frame that splits the original data frame by year.

```
years <- group_by(chicago, year)</pre>
```

Finally, we compute summary statistics for each year in the data frame with the summarize() function.

```
summarize(years, pm25 = mean(pm25, na.rm = TRUE), o3 = max(o3tmean2,
   na.rm = TRUE), no2 = median(no2tmean2, na.rm = TRUE))
## # A tibble: 19 x 4
##
      year pm25
                     03
                          no2
      <dbl> <dbl> <dbl> <dbl> <dbl>
##
## 1 1987 NaN
                   63.0 23.5
##
   2 1988 NaN
                   61.7 24.5
## 3 1989 NaN
                   59.7 26.1
## 4 1990 NaN
                   52.2 22.6
```

```
## 5 1991 NaN
                 63.1 21.4
## 6 1992 NaN
                 50.8 24.8
  7 1993 NaN
                44.3 25.8
##
                52.2 28.5
## 8 1994 NaN
                66.6 27.3
## 9 1995 NaN
## 10 1996 NaN
                 58.4 26.4
## 11 1997 NaN
                 56.5 25.5
## 12 1998 18.3 50.7 24.6
## 13 1999 18.5 57.5 24.7
## 14 2000 16.9 55.8 23.5
## 15 2001 16.9 51.8 25.1
## 16 2002 15.3 54.9 22.7
## 17 2003 15.2 56.2 24.6
## 18 2004 14.6 44.5 23.4
## 19 2005 16.2 58.8 22.6
```

group_by()

In a slightly more complicated example, we might want to know what are the average levels of ozone (o3) and nitrogen dioxide (no2) within quintiles of pm25. A slicker way to do this would be through a regression model, but we can actually do this quickly with group_by() and summarize().

First, we can create a categorical variable of pm25 divided into quintiles.

```
qq <- quantile(chicago$pm25, seq(0, 1, 0.2), na.rm = TRUE)
chicago <- mutate(chicago, pm25.quint = cut(pm25, qq))</pre>
```

Now we can group the data frame by the pm25.quint variable.

```
quint <- group_by(chicago, pm25.quint)
## Warning: Factor `pm25.quint` contains implicit NA, consider using
## `forcats::fct_explicit_na`</pre>
```

Finally, we can compute the mean of o3 and no2 within quintiles of pm25.

```
summarize(quint, o3 = mean(o3tmean2, na.rm = TRUE), no2 = mean(no2tmean2,
   na.rm = TRUE))
## # A tibble: 6 x 3
##
    pm25.quint
                  03
                        no2
##
    <fct>
                <dbl> <dbl>
## 1 (1.7,8.7]
                 21.7 18.0
## 2 (8.7,12.4]
                 20.4 22.1
## 3 (12.4,16.7] 20.7 24.4
## 4 (16.7,22.6] 19.9 27.3
## 5 (22.6,61.5] 20.3 29.6
## 6 <NA>
            18.8 25.8
```

%>%

The pipeline operator %>% is very handy for stringing together multiple dplyr functions in a sequence of operations.

```
third(second(first(x)))
```

This nesting is not a natural way to think about a sequence of operations. The %>% operator allows you to string operations in a left-to-right fashion, i.e.

```
first(x) %>% second %>% third
```

%>%

Take the example that we just did in the last section where we computed the mean of o3 and no2 within quintiles of pm25. There we had to

- 1. create a new variable pm25.quint
- 2. split the data frame by that new variable
- 3. compute the mean of o3 and no2 in the sub-groups defined by pm25.quint

That can be done with the following sequence in a single R expression.

```
mutate(chicago, pm25.quint = cut(pm25, qq)) %>% group_by(pm25.quint) %>%
   summarize(03 = mean(03tmean2, na.rm = TRUE), no2 = mean(no2tmean2,
       na.rm = TRUE))
## Warning: Factor `pm25.quint` contains implicit NA, consider using
## `forcats::fct_explicit_na`
## # A tibble: 6 x 3
##
   pm25.quint o3
##
    <fct>
            <dbl> <dbl>
## 1 (1.7,8.7]
                21.7 18.0
## 2 (8.7,12.4]
                 20.4 22.1
## 3 (12.4,16.7] 20.7 24.4
## 4 (16.7,22.6] 19.9 27.3
## 5 (22.6,61.5] 20.3 29.6
## 6 <NA>
          18.8 25.8
```

Summary

The dplyr package provides a concise set of operations for managing data frames. With these functions we can do a number of complex operations in just a few lines of code. In particular, we can often conduct the beginnings of an exploratory analysis with the powerful combination of group_by() and summarize().

- dplyr can work with other data frame "backends" such as SQL databases. There is an SQL interface for relational databases via the DBI package
- dplyr can be integrated with the data.table package for large fast tables

The dplyr package is handy way to both simplify and speed up your data frame management code. It's rare that you get such a combination at the same time!

Lab Session

dplyr

You'll be working with the airquality in the R package datasets. Bear in mind %>%.

- 1. Please return all the rows where Temp is larger than 80 and Month is after May.
- 2. Please add a new column that displays the temperature in Celsius.
- 3. Calculate the mean temperature in each month.
- 4. Remove all the data corresponding to Month = 5, group the data by month, and then find the mean of the temperature each month.
